Contract No. NAS 8-33424

SPRAGUE ELECTRIC COMPANY  
North Adams, Mass. 01247  
March 20, 1980

## SECTION I

### ABSTRACT

Approximately seven hundred (700) 47  $\mu$ f/35 Volt capacitors were manufactured and tested in accordance with Alternate A of the proposal submitted and ultimately formalized as NASA Contract NAS 8-33424. As the various read-out intervals occurred, the data was forwarded, as required, for information and evaluation. The 2000 hour data is part of this report.

SECTION 2  
DISCUSSION

1. GENERAL

Prior to the receipt of this contract, the use of surge current screening of solid tantalum capacitors had been used to minimize turn-on type failures in high current circuits. There was little background as to its effectiveness under conditions of continuous turn-ons at elevated temperatures representing extended life conditions. This included the use of surge current screening in accordance with Mil-C-39003/3 as well as other user and manufacturer surge current test procedures.

It is the objective of this contract to determine the effectiveness of short term surge current screening on solid tantalum capacitors and to measure its effect on parameters from 120 Hz to 40 KHz.

2. PROGRAM OF TEST

- a. 47 mfd - 35 volt capacitors were manufactured in the Sprague Electric, Concord, New Hampshire, facility in a line qualified to "S" level of Mil-C-39003D.

After standard HYREL burn-in, Weibull proof testing, and DCL screening for 3 sigma distributions, 700 capacitors were received for test which represented two different sub lots.

- b. The specialized test equipment was funded and manufactured "in house" by Sprague Electric.
- c. The parts were suitably identified with this contract and were serialized.
- d. A total of 528 parts were divided into two groups, designated "controls", and "surge current screened".
- e. Surge current screened parts were exposed to five cycles of surge current at 25°C, -55°C and +85°C prior to start of the test matrix.
- f. Each major group of 264 parts was subdivided as follows: (See Figure 1)

|                  |       |          |           |
|------------------|-------|----------|-----------|
| Life Test        | 125°C | 23 Volts | 48 pieces |
| Life Test        | 125°C | 0 Volts  | 48 pieces |
| Life Test        | 85°C  | 35 Volts | 72 pieces |
| Cycled Life Test | 125°C | 23 Volts | 96 pieces |

All parts were mounted on 24 position test boards with a 1 amp fast blow fuse in series with each capacitor so that the only resistance between the power source and any of the capacitors was the fuse resistance of 0.2 ohms in series with each capacitor.

- g. After mounting on test boards, capacitance, DF, and ESR was measured at 120 Hz, 1 KHz, and 40 KHz as well as DC leakage at 25°C and 85°C.

DCL @ 25 & 85 C

**FIGURE 1**

h. The "Cycled Life Test" was run as follows:

125°C    Constant thru test matrix  
23V      Cycled "on" for 50 minutes and "off" for 10 minutes  
17amp    Power Supplies  
120000   Mfd energy storage banks  
300      Ampere peak current on charge into 1 board of 24 capacitors  
         at a time.  
40       Microseconds to 300 ampere peak currents on "charge".  
5 to 7%   Voltage overshoot

"Off" condition is discharge thru a short circuit

Figures 3 and 4 show the inrush current peak and voltage build up.

### 3. RESULTS OF 2000 HOUR TEST PROGRAM

The results of all of the testing is summarized in Tables 1 thru 4 and Figures 2, 5 through 20.

The format provides average values and standard deviations of the parameters, capacitance, dissipation factor and equivalent series resistance at 120 Hz, 1 KHz and 40 KHz.

DC leakages at 25°C and 85°C are shown in median values and ratios of maximum to median values which indicates the dispersion of the distribution.

#### Table 1, 85°C 35 Volt Life Test

This summary shows no significant difference to exist between the controls and surge current screened parts.

#### Table 2, 125°C 23 Volt Life Test

In the control group, 1 blown fuse occurred at 1000 hours and 2 more at 2000 hours for a cumulative total of 3 failures, while the surge screened group had no failures. This result seems to indicate a beneficial effect from surge current screening.

Failure analysis indicated no assignable reason for the failures to have occurred.

Failures at 125°C and 23 volts were unexpected, but it should be remembered that these parts were run without a 3 ohm resistance in series as specified in Mil-C-39003, and had only a 0.2 ohm 1 ampere fast blow fuse in series with each part.

Since the definition of failure is a blown fuse irrespective of electrical parameters, one should consider the parameters on the three failed parts, Which indicates 2 of the 3 blown fuse failures parts still meet all Mil-C-39003 electrical limits.

The definition of a failure by one blown 1 ampere fuse is a worse case failure definition which occurs during a dielectric scintillation, since in some cases the dielectric will self heal after the first fuse blow.

### Table 3, 125°C 0 Volt Shelf Test

Table 3 shows the high temperature storage or zero voltage shelf test results.

There does not appear to be any significant parameter differences between the controls and the surge current screened parts.

### Table 4, 125°C 23 Volts Cycled Life Test

Table 4 provides the summary of the surge current cycled life test.

The failures tabulated in this Table are more definitively shown in Figure 2.

Figure 2 shows diagrammatically, the location of each test board in the oven, i.e., boards 1 and 5 being side by side at the top of the oven and boards 4 and 8 being side by side at the bottom of the oven. Each block shown as a "board" indicates the number of failures as a fraction, i.e., "2/24" meaning that 2 pieces out of the 24 on the board failed. The numerical "hours" indicates approximate times into the test that failures occurred, since the failures denoted by LED's, were not visually monitored between 5 PM and 8 AM weekdays, and 5 PM Friday to 8 AM Monday, but the time indications are never the less, of considerable interest as compared to the normal life test readouts.

Performance differences indicated by blown fuses in the cycled life tests are more significant than for the normal life tests.

On the "Cycled Life Test", one board at a time was energized from the energy storage banks so each board saw a fast 40 microsecond charge of about 300 amperes peak, for 2000 charges at 23 Volts and 125°C, during the 2000 hour test.

Results after 2000 hours show:

| <u>Control Group</u> | <u>Surge Screened Group</u> |
|----------------------|-----------------------------|
| 4 Failures out of 96 | 8 Failures out of 96        |

however, comparing sublots:

| <u>Sublot</u> | <u>Control Group</u> | <u>Surge Screened Group</u> |
|---------------|----------------------|-----------------------------|
| 919825        | 3 Failures out of 48 | 8 Failures out of 48        |
| 919827        | 1 Failure out of 48  | 0 Failures out of 48        |

Comparing surge current cycling failure rates observed in the testing performed as outlined above with the Weibull (non-cycled) failure rate analysis performed on each of the sublots indicates the following:

| <u>Sublot</u> | <u>Control Group</u> | <u>Screened Group</u> | <u>Weibull</u>   |
|---------------|----------------------|-----------------------|------------------|
| 919825        | 4.17%/1000 Hrs       | 9.38%/1000 Hrs.       | 0.0021%/1000 Hrs |
| 919827        | 2.08%/1000 Hrs       | 1.04%/1000 Hrs.       | 0.0085%/1000 Hrs |

The above results appear to be contradictory unless one remembers that static testing (Weibull) is being compared to dynamic testing (cycled life).

**CYCLED LIFE TEST**  
**Blown Fuse Failures After 2000 Hours 125°C**

As previously explained, Figure 2 shows diagrammatically the location of the test boards in the oven. At the 500 hour readout of the cycled life test, a temperature profile was made on the top boards where early failures was noted. The top two boards were found to have been running at 135°C instead of 125°C due to radiation from the heaters at the top of the oven. Heat baffles were installed after 500 hours so that all boards operated at 125°C after that.

#### 4. GENERAL OBSERVATIONS

- a. 40 KHz capacitance increased almost 10% on all 125°C tests with most of the increase occurring before 250 hours.
- b. 40 KHz capacitance increased only 2.5% on the 85°C tests with most of the increase occurring before 250 hours.
- c. 120 Hz capacitance remained almost unchanged on both 85°C and 125°C tests.
- d. Equivalent series resistance (ESR) at 40 KHz remained almost unchanged on all tests including the severe cycle life tests with the high current charging and discharging.
- e. D.C. leakage at 25°C, decreased on all tests except the 125°C, zero voltage shelf test where it increased by a factor approaching 5 times.
- f. D.C. leakage at 85°C decreased on all tests except the 125°C, zero voltage shelf test where it increased more than 1.5 times its original value.
- g. D.C. leakage degradation on the 125°C, zero voltage shelf test has a much greater effect on the lower levels of DCL at 25°C than on the higher +85°C DCL levels.

#### 5. CONCLUSIONS

1. The cycled life test appears to indicate that surge current screening did not improve the performance of parts on the steady 125°C on/off test and that the controls had less failures.

Analysis of the numbers of failures statistically however, shows that the difference between the two sides is not significant.

Separation of the two sides of the test into their respective sublots does indicate that one lot is superior to the other lot on the cycled life test, even though our standard methods of lot evaluation indicated just the opposite.

The results on the cycled life test would likely have been more definitive if the surge current screening and cycled life tests were performed on the same equipment and over the same low to high temperature range with continuous monitoring of all events, temperatures, currents and voltages thru out the 2000 hours.

2. The cycled life test appears to indicate that performance differences can exist between the two sublots that made up the matrix even though normal sublot testing, Weibull accelerated testing and conventional 85°C and 125°C life testing did not indicate that these sublots were different. The details shown in Figure 2 would make it appear that surge current screening aggravated subplot 919825 since there were eight failures out of 48 pieces

(8/48) which were surge current screened and only three failures out of 48 pieces (3/48) which were not surge current screened. In the case of subplot 919827 the opposite appeared to occur. That is, there were no failures out of 48 pieces (0/48) which were surge current screened, while there was one failure out of 48 pieces (1/48) which were not surge current screened. From a statistical point of view, there is no significant differences between 0/48 and 1/48 if no other information is available. This is not true when comparing 8/48 with 3/48.

The differences between the two sublots could have been significantly affected by a temperature gradient problem encountered early in the test program. It was found that the upper test boards were subjected to approximately 135°C during the first 500 hours. This may have a bearing on the difference between the sublots but not between screened and non-screened test boards.

It should be kept in mind that the surge current screening was done at -55°C, +25°C and +85°C whereas the cycled life test was performed at +125°C. Had the cycled life tests repeated the same temperature excursions as the surge current screening test, the results may have been more sharply defined.

3. The design of the surge current test facility for maximum current inrush while minimizing voltage overshoot was achieved as shown in Figures 3 & 4. These are typical of the results achieved on allboard positions. It can be seen that an average of about 14 amps peak inrush per capacitor was reached in about 40 microseconds with only about 5 to 7% voltage overshoot. This rate of rise of current with respect to time is much higher than would be encountered in actual applications, thus a more severe test condition.
4. Overall, it is not realistic to attempt to draw a firm conclusion as to the effectiveness of a surge current screen on solid tantalum capacitors based on the conditions described herein because of the small number of failures.

#### 6. RECOMMENDATIONS

In order to provide a more realistic and definitive evaluation of surge current screening, it appears that the cycled life test should be modified to include temperature cycling as well as voltage cycling. Since mechanical stresses on the dielectric are proportional to the square of the voltage applied, it appears that a more severe set of conditions would be desirable to determine if this was a factor in "turn-on" failures. Therefore, it is recommended that full rated voltage at 85°C be used instead of two-thirds rated voltage at 25°C. Further, since the surge current screening was performed at -55°C, +25°C and +85°C, to more nearly approximate actual use conditions, the temperature cycling during life should also cover the same extremes of temperature of -55°C and +85°C. An engineering change proposal has been submitted covering these recommendations.
